

FIREWALL

Temat 1.

franz-bonaparta.github.io

FIREWALL?

Firewall (zapora sieciowa) to cyfrowy ochroniarz, który stoi na straży Twojego komputera lub serwera i pilnuje bezpieczeństwa w sieci. System operacyjny posiada tysiące wirtualnych drzwi, zwanych portami, przez które przepływają różne dane (np. strony WWW czy przesyłane pliki). Zapora działa według prostej listy reguł – sprawdza ruch wchodzący do komputera oraz wychodzący na zewnątrz. Jeśli wykryje nieznane lub zablokowane przez Ciebie połączenie, natychmiast zatrzaskuje te drzwi przed nosem, chroniąc system przed zagrożeniami.

KIERUNKI RUCHU

- Zapora sieciowa dzieli cały ruch sieciowy na dwa główne kierunki, których pilnuje osobno. Ruch przychodzący (Inbound) to wszystkie połączenia, które próbują dostać się z sieci zewnętrznej do wnętrza naszego serwera.
- Z kolei ruch wychodzący (Outbound) to dane wysyłane z naszego serwera na zewnątrz, na przykład podczas przeglądania stron internetowych.

PORTY SIECIOWE

- Port 80 (HTTP) – ruch odpowiedzialny za zwykłe strony internetowe.
- Port 443 (HTTPS) – ruch dla bezpiecznych, szyfrowanych stron WWW.
- Port 21 (FTP) – ruch służący do przesyłania plików na serwer.
- Protokół ICMP (Ping) – specjalny ruch diagnostyczny (nie ma numeru, wybiera się go jako osobny protokół), który służy do sprawdzania, czy komputery w ogóle się „widzą”.

ODBLOKOWANIE PORTU

Robi się dokładnie tak samo jak blokowanie. Przechodzisz przez ten sam kreator, wybierasz ten sam protokół (np. TCP) i wpisujesz ten sam numer portu. Jedyna różnica polega na tym, że na samym końcu zamiast opcji Zablokuj połączenie (Block), klikasz Zezwól na połączenie (Allow). Cała reszta jest identyczna!
